The pyramids attest to the engineering genius of Ancient Egypt. They are the most famous examples of this. The largest Egyptian pyramids are the Great Pyramids of Giza, which are still standing today.

The Ancient Egyptians built at least 97 pyramids, which were used as tombs for pharaohs and other important people. The pyramids were built using a combination of stone, mud bricks, and wood.

The pyramid of Cheops, the oldest and largest of the three pyramids of Giza, was begun by Pharaoh Khufu around 2580 BC. It is made of 2.3 million stone blocks and weighs approximately 5.5 million metric tons. The pyramid has an estimated height of 147 meters.

The pyramid of Chephren, the second largest of the Giza pyramids, was built by Pharaoh Khafre around 2560 BC. It is made of 2.2 million stone blocks and weighs approximately 4.5 million metric tons. The pyramid has an estimated height of 143 meters.

The pyramid of Mycerinus, the smallest of the three pyramids of Giza, was built by Pharaoh Mycerinus around 2550 BC. It is made of 1.4 million stone blocks and weighs approximately 2.5 million metric tons. The pyramid has an estimated height of 140 meters.

The pyramids were built using a combination of stone, mud bricks, and wood. The stones were cut using copper tools, and the wood was used to hoist the stones into place.

The pyramid of Cheops is still intact and stands as a testament to the engineering prowess of the Ancient Egyptians. The pyramid of Chephren is partially collapsed, but can still be seen today. The pyramid of Mycerinus is mostly collapsed, but its base can still be seen.

The pyramids were built as tombs for pharaohs and other important people. The pharaohs were believed to be gods, and their tombs were designed to provide them with everything they would need in the afterlife.
